Developing Innovative Tools to Incentivise Sustainable Cattle Ranching

Dr Rod Greder
Pasture-based Animal Production

Pasture-based systems offer a more sustainable way to raise cattle and use land that is not suitable for crop production. On these farms, cattle roam pastures and graze on grass and other plants while depositing manure in the field where it is needed. This can translate to healthier animals, fewer veterinary bills, and more nutritious meat and milk.

Well-managed farms distribute animals across the pasture, spreading their manure more evenly and improving the quality of the grass, which in turn reduces soil erosion and water pollution. Rotational grazing can build rich soils that conserve water and are sustainable for decades of use. These myriad benefits make well-managed pastures more resilient in the face of climate change.

However, the way in which a pasture-based farm is managed dictates whether the system is net beneficial to the environment. To truly adopt best management practices, farmers must make sizable financial and time investments – costs that some farmers cannot absorb.

Dr Greder realised that many of the most common complaints associated with intensive pasture management focus on inefficient practices that could be improved with easy-to-use, simple tools. With the goal of increasing the adoption of pasture-based systems, Dr Greder’s novel tools can make the lives of ranchers easier. His innovative methods also promote and strengthen the most environmentally friendly aspects of pasture-based farms, while providing measurement tools to document quantity and quality benefits of intensive rotational grazing. These tools allow ranchers to test different management practices and gather data to confirm that they are sustainable and cost-effective.

Pasture Productivity Pail

While working at the University of Minnesota, Dr Greder pioneered a study to create affordable, easy-to-use tools to document how different grazing methods can improve soil health and water quality. Currently, most ranchers use qualitative assessments to evaluate the benefits of grazing systems, which are often inaccurate. With a science-driven tool that provides hard data on the benefits of grazing management, best practices might be more readily adopted by hesitant farmers.

With funding from the United States Department of Agriculture (USDA), Dr Greder began a three-year project. He collaborated with ranchers to create a mobile, easy-to-use tool that measures important soil characteristics, including fertility, temperature and moisture, and above ground forage quantity and quality.

After three years of working with ranchers, Dr Greder and his colleagues created the ‘Pasture Productivity Pail’ – a set of portable tools carried in a bucket, which is used to make informed decisions on pasture management. The Pasture Productivity Pail includes resources that measure important soil characteristics, quantify forage quality and quantity, and provide information for ranchers to identify and manage weeds and optimise thicker plant stands and more beneficial plant mixtures.

‘We identified a set of comprehensive, easy to use tools that a rancher can take to the field and determine the quality and quantity of their pasture forages,’ says Dr Greder. ‘This provides data that they can use to make fact-based decisions on how to choose...’
best management practices that result in improved pasture output, animal productivity, farm profitability and environmental sustainability. This pail also becomes an in-field awareness tool that ranchers can use to educate themselves and staff about all aspects of forage production and optimisation.

As part of his research, Dr Greder interacted with many ranchers, asking them for insight on what management practices could result in greater productivity. Many ranchers and grazing experts have shown that more frequently moving cattle stimulated soil health and spread manure in more sustainable ways, improving forage productivity. However, anywhere that cattle go, critical equipment must follow, which can be cumbersome for the rancher. This common complaint inspired Dr Greder’s next innovation – a way to transport necessary equipment across a pasture more easily.

**Mobile Grazing Unit to Transport Equipment**

Rotational grazing describes the practice of moving cattle to different portions of the pasture, allowing each area of a farm to have rest periods without grazing. Well-managed rotational grazing allows both the roots and shoots of the forage to recover and grow more vigorously.

However, the benefits of rotational grazing are not free. Ranchers must consider the expenses of rotational grazing, including more fencing, more labour and more intricate watering systems. Although these trade-offs are generally acceptable to ranchers, Dr Greder realised that few resources discuss the physical hassle of moving supplies across the pasture.

When thinking about his own farm, Dr Greder realised that he often reduces the frequency of cattle rotations to save the hassle of moving equipment. This revealed yet another weak point in pasture-based management that could be eliminated with creative, innovative tools.

In another project funded by the USDA, Dr Greder surveyed ranchers to design a mobile unit that can be easily transported across a pasture with standard farm equipment, such as a tractor or truck. The mobile cart contains critical equipment that farmers need to move along with their cattle, such as mineral stations, water troughs, fly control, fencing supplies and optionally, shade protection. After several iterations of prototypes that incorporated rancher feedback, Dr Greder is currently in the final stages of preparing his mobile cart for commercial sale.

**More Pasture-Based Operations**

Dr Greder has leveraged his decades of experience in agricultural research and a lifetime of working on farms to identify and address critical problems that are unique to pasture-based systems. The Pasture Productivity Pail and Mobile Grazing Cart are easy-to-use tools that will immediately make life easier for ranchers who are trying to manage their pastures in more sustainable and productive ways. By removing these small yet persistent obstacles and by providing easy-to-use tools, Dr Greder has made pasture-based cattle ranching a more attractive option. When adopted at a large scale, his innovations will help to make cattle production more sustainable, allowing farmers to stay in businesses while also protecting the environment for future generations.
Meet the researcher

Dr Rod Greder
Sustainable Agriculture Extension Agent
University of Florida IFAS Extension
Sarasota, FL
USA

Dr Rod Greder has been surrounded by agriculture for his entire life. Raised on a 500-acre beef, corn and hay farm in Iowa, Dr Greder is no stranger to life as a rancher. As a researcher, he decided to continue focusing on agriculture, and he received his PhD in Plant Genetics from the University of Illinois. His work has varied from managing his 83-acre farm to conducting seed research. His current work focuses on designing products that make managing pasture-based livestock ranches more profitable, sustainable, and accessible. Dr Greder draws inspiration from other ranchers and his experience rearing cows on his pasture in Pine County, Minnesota. After living in Minnesota for 30 years, Dr Greder left his position at the University of Minnesota Extension program to work at the University of Florida Institute of Food and Agriculture Extension.
